Ephemeral Wetlands may also be referred to as ephemeral ponds, seasonal ponds, temporary ponds or vernal pools.

Ephemeral wetlands are depressional wetlands that temporarily hold water in the spring and early summer or after heavy rains. Periodically, these wetlands dry up, often in mid to late summer. They are isolated without a permanent inlet or outlet, but may overflow in times of high water. Ephemeral Wetlands are free of fish, which allows for the successful breeding of certain amphibians and invertebrates.

- The treasured wildlife that depend on ephemeral wetlands.
- Threats facing ephemeral wetlands.
- How you can help.
Wood frog tadpoles are in a race against time. They have to find food, grow, avoid predators and begin to develop into frogs before the wetland dries up (Tyning, 1990).

Female wood frogs lay up to a thousand eggs in rounded masses about the size of a tennis ball. The eggs are attached to small twigs and branches just under the surface of the water (Tyning, 1990).

In early spring wood frogs migrate from their nearby woodland habitat to ephemeral wetlands in search of water.

Wood frogs over-winter in leaf litter, old logs and small burrows. They avoid freezing due to an anti-freeze like compound in their bodies.

Many amphibians hibernate in the surrounding upland habitat during the winter months.

By mid-summer the wetland begins to dry out and the surrounding upland habitat becomes critical for the newly emerging amphibians.

Wood frog tadpoles grow in a race against time. They have to find food, grow, avoid predators and begin to develop into frogs before the wetland dries up (Tyning, 1990).

Spore they emerge from the water, the wood frogs will spend the rest of the year in the nearby woodland.

By fall there are very few traces of the once productive wetland. This dry phase eliminates fish and completes the life cycle for insects like Fairy Shrimp whose eggs require a dry period to be viable next spring.

Snow melt and spring rains fill ephemeral wetlands providing breeding habitat for many amphibians and aquatic insects. The developing larvae provide an important food source for migrating birds.

Female wood frogs lay up to a thousand eggs in rounded masses about the size of a tennis ball. The eggs are attached to small twigs and branches just under the surface of the water (Tyning, 1990).

**Ephemeral Wetlands are:**

- not well protected under current regulations.
- not well understood.
- difficult to identify when they dry out.
- as small as six – twelve feet across.
- often converted to other uses such as detention ponds, fish ponds, agriculture, or dump sites.
- usually isolated from permanent waterbodies.
- occasionally protected but the surrounding upland habitat is usually destroyed.
- threatened by invasive plant species.
- being lost across the Midwest.
- critical habitat for many wildlife species.
- important to migrating birds.
- important for flood control and water quality.

**Protection Issues:**

Ephemeral wetlands are hard to define, identify and protect because they tend to be small, isolated and certain times of the year do not hold water. These wetlands tend to be highly productive. They warm quickly in spring and produce abundant quantities of food resource for developing amphibians, reptiles and migrating birds. Even small sites, much less than an acre, can produce hundreds of frogs, toads and salamanders. They also provide critical links to other wetlands and populations. This immense ecological value is difficult to translate into legal protection which varies state to state.

**Conversions:**

- Many of our small ephemeral wetlands have been drained and filled to facilitate agriculture, building new subdivisions or other development.
  
  This not only eliminates habitat, but also increases the risk of local flooding.

- Others have been excavated to construct stormwater detention ponds.

  During rain storms pollutants are washed into these ponds.

- Still others have been converted to permanent ponds for raising fish and other forms of aquaculture.

  Permanent bodies of water tend to support fish that prey on amphibian eggs, tadpoles and aquatic insects.

**Savannah/Open Woodland**

Although a wetland itself may not be altered, without the surrounding upland habitat the wetland will not continue to be productive and species such as reptiles and amphibians will eventually be lost. Many creatures that depend on ephemeral wetlands for some part of their life cycle need the surrounding habitat just as much. Frogs, toads and salamanders breed in the wetland but generally feed and spend most of the year in the upland. Turtles will feed in the wetland but require uplands for nesting.

Amphibians and reptiles that utilize ephemeral wetlands, such as the one circled in blue above, need intact upland habitat. Roads, cars, houses, and buildings create barriers and hazards to migration for wildlife and directly impact important habitat. These wetlands need to remain linked by continuous upland habitat to other wetlands and populations.

Upland habitat usage for a typical amphibian is represented by the green circle in the photograph above. The spotted salamander migrates at least 490 feet from the wetland to spend most of the year feeding and hibernating in the upland habitat. Some species such as Blanding’s turtles and leopard frogs may travel up to a mile or more away from the waterbody.
Ephemeral Wetlands
So, Who Cares? YOU SHOULD!
Wildlife are depending on you for protection.
EPHEMERAL WETLAND CONSERVATION

Things you can do to protect and preserve Ephemeral Wetlands:

- Support the protection of these wetlands and their surrounding habitat.
- Visit ephemeral wetlands in your area — experience their uniqueness.
- Volunteer for local restoration efforts — contact local conservation organizations.
- Consider long-term protection options for wetlands on your private property such as conservation easements — contact your local land trust.
- Start a register of ephemeral wetlands in your area (www.vernalpool.org)
- Participate in local amphibian monitoring programs like frog calling surveys and herp atlas projects coordinated by local conservation organizations.
- Join local conservation organizations involved in wetland protection.
- Visit USEPA Region 5 website for more information on ephemeral wetlands:

- Visit the Partners for Amphibian & Reptile Conservation (PARC) Midwest/Center for Reptile and Amphibian Conservation and Management website for additional information on Ephemeral Wetlands and how to get more copies of this brochure at: http://herps.ipfw.edu/wetlands/ephemeral/

For information on wetland regulations contact your state natural resource agency or county Soil & Water Conservation District.
